Fundamentals of robot navigation

Cecilia Laschi The BioRobotics Institute Scuola Superiore Sant'Anna, Pisa

cecilia.laschi@santannapisa.it

http://didawiki.cli.di.unipi.it/doku.php/magistraleinformatica/rob/start

Outline of the lecture

- Fundamental problems of robot navigation
- Maps and environment models
 - Metric maps and topological maps
- Planning techniques
 - Path Planning and Path Following
- Localization methods and systems
 - Odometry and systems based on active beacons and landmarks

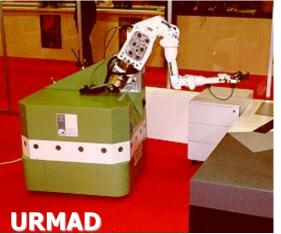

J.C. Latombe, *Robot Motion Planning*, Kluwer Academic Publishers, 1991

Robot mobile bases

Pioneer I – Real Word Interface, USA

DustBot

B21r – Real Word Interface, USA

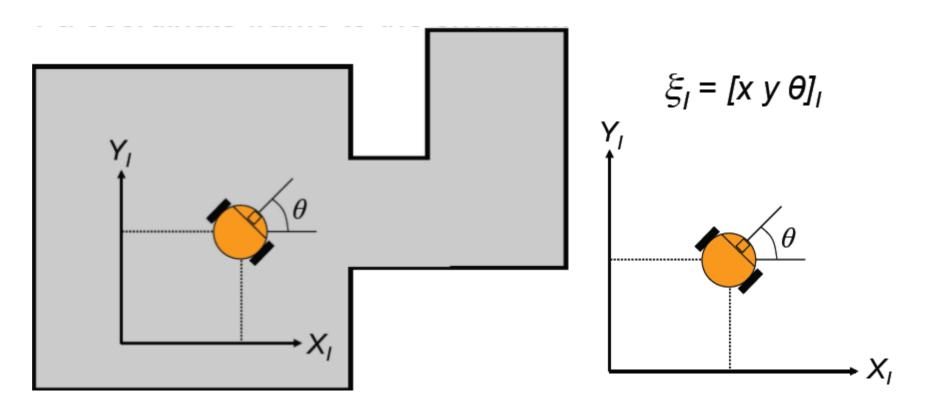

Outline of the lecture

- Fundamental problems of robot navigation
- Maps and environment models
 - Metric maps and topological maps
- Planning techniques
 - Path Planning and Path Following
- Localization methods and systems
 - Odometry and systems based on active beacons and landmarks

J.C. Latombe, *Robot Motion Planning*, Kluwer Academic Publishers, 1991

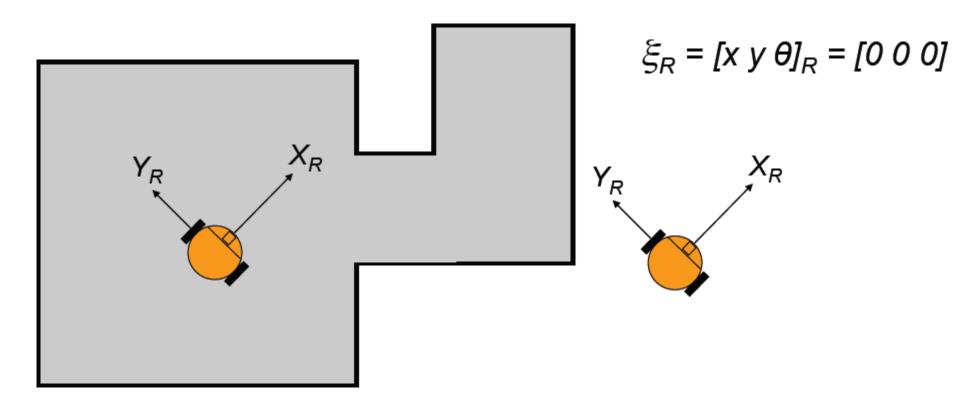

Mobile robot position

World reference frame

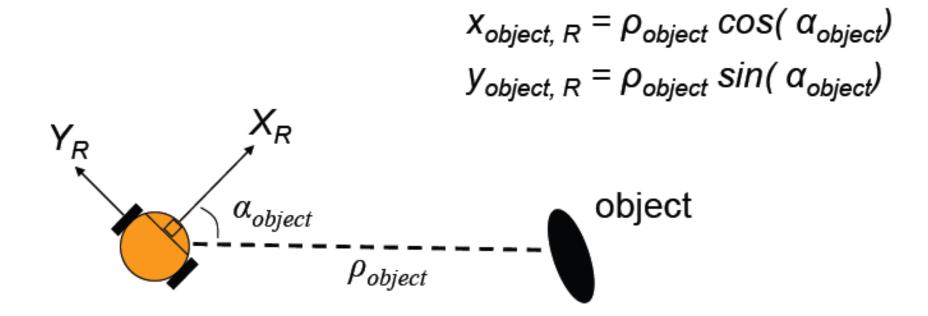

Mobile robot position

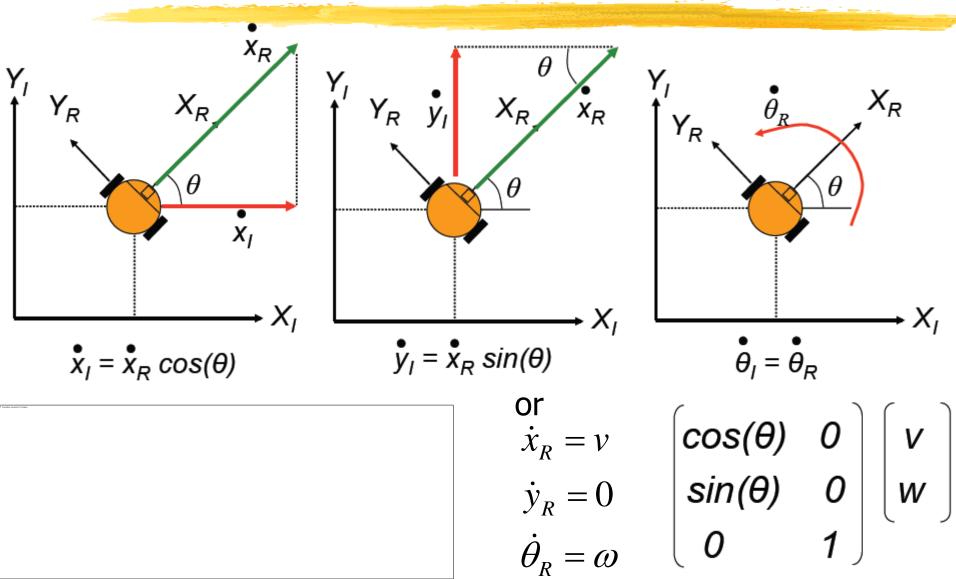

Robot reference frame

Obstacle position

Transformations between the world reference frame and the robot reference frame, in velocity space

Robot navigation problem

To reach a final position from a starting position, given in geometric or sensory terms, avoiding obstacles

The classical questions to solve are:

- Where am I?
- Where are the other objects around me?
- How can I reach a desired position?

Classical approach

In the classical approach, the answers are:

- Localization: geometric position (x,y,θ coordinates in an absolute reference system) or sensory state in the robot environment
- Maps or Models: environment formalization and representation
- Planning: planning of robot movements in the environment

Reactive systems

- In reactive systems robots interact with the world through sensors and actuators.
- Knowledge is not modelled nor stored, but it is extracted `on-line' from the world itself, through sensors.
- The robot behaviours are defined as reactions to the information perceived from the environment.
- Only the second and third questions are relevant and the answers are given in terms of actions.

Outline of the lecture

- Fundamental problems of robot navigation
- Maps and environment models
 - Metric maps and topological maps
- Planning techniques
 - Path Planning and Path Following
- Localization methods and systems
 - Odometry and systems based on active beacons and landmarks

Maps and world representation

Metric Maps (Geometric):

they represent the objects in the world on the basis of their size and coordinates in the absolute reference frame

Topological Maps:

they represent the objects in the world (points of interest) on the basis of their characteristics and of the relations among them

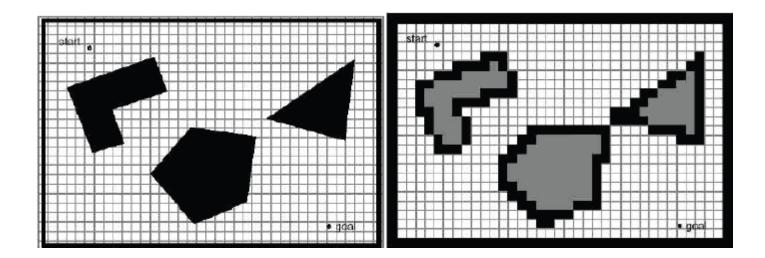

Geometric maps

Main methods for world representation through metric maps:

- Occupancy grid
- Geometric description

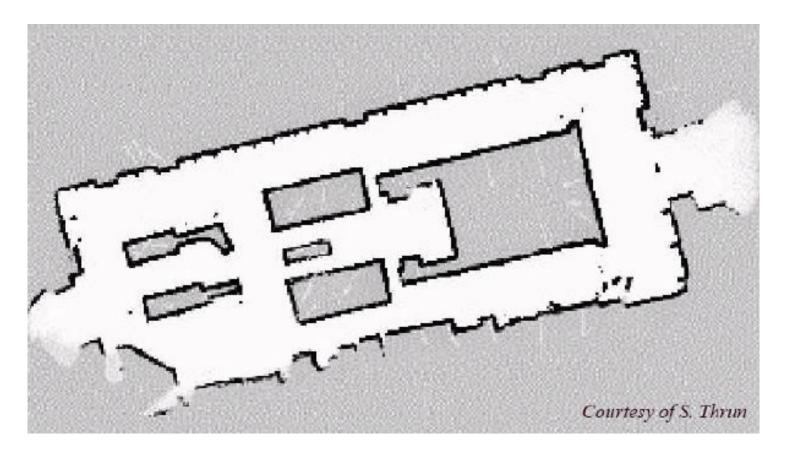

Occupancy Grid

- The environment is represented on a bidimensional grid.
- A value is associated to each grid element, which indicates the cell state (free/occupied)

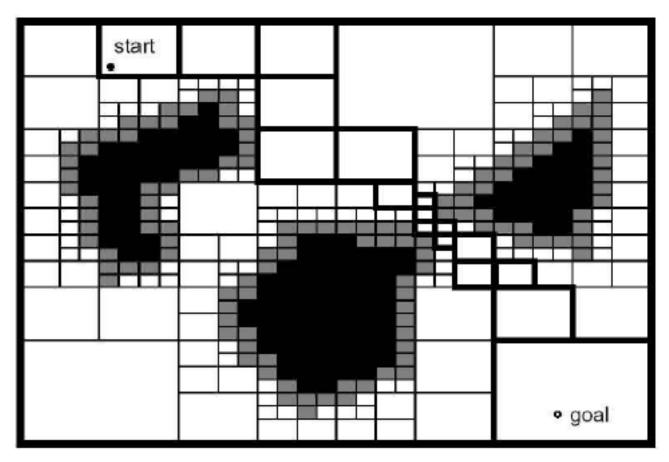

Occupancy Grid

Fixed grid

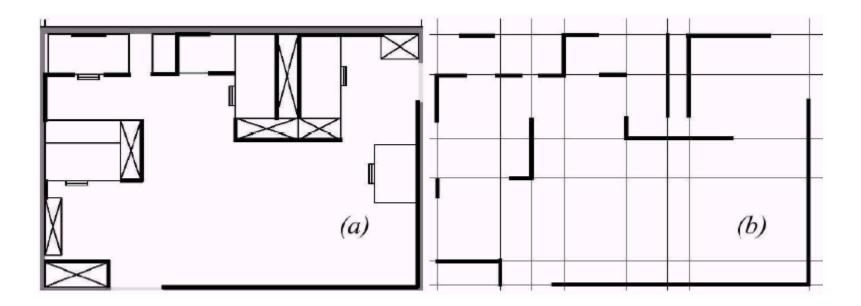

Occupancy Grid

Variable grid

Geometric description

 The environment is represented through a geometric description, usually in terms of segments, obstacles and free space.

Topological maps

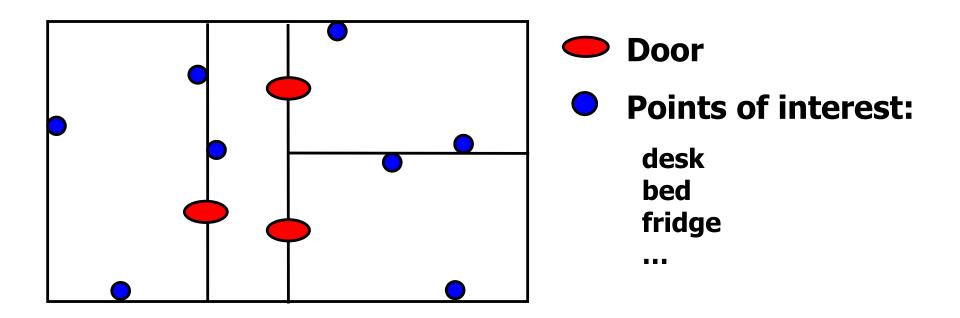

- The environment is defined in terms of points of interest, relevant for the robot, and of the relations among points of interest.
- A point of interest is an object (natural or artificial) which is relevant for robot navigation (e.g. walls, doors) or for robot tasks (e.g. tables, beds, appliances).
- A point of interest can be defined by a position in the robot space or by a sensory state.

Topological maps

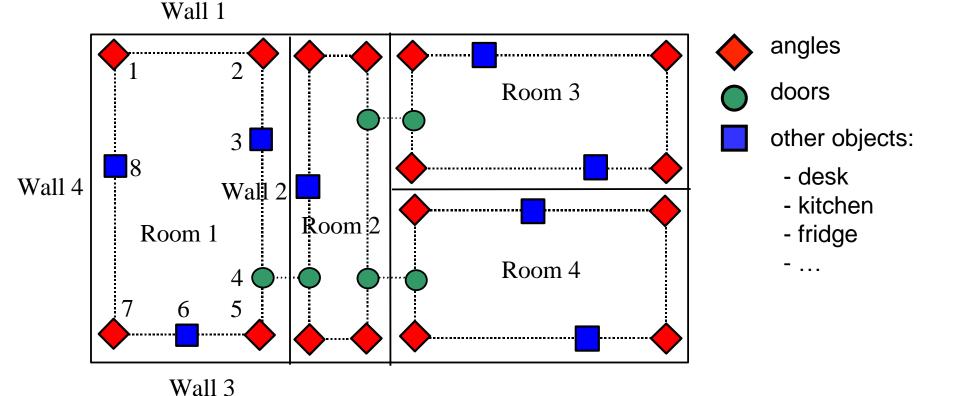

Topological maps

Example: map of a home environment with some points of interest

Representation of a topological map through a graph

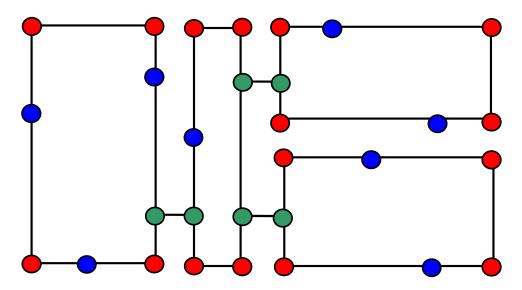

- Assign a number to each room
- For each room, number the walls clockwise
- For each wall, number the points of interest clockwise

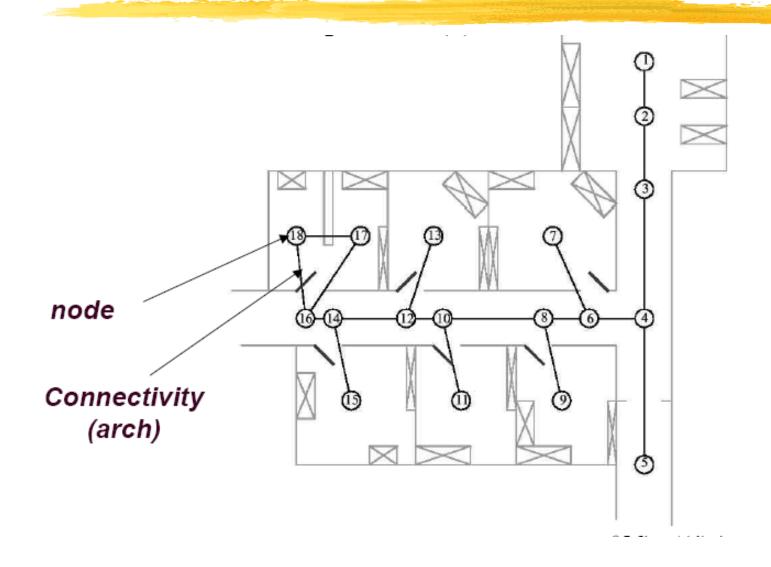

Representation of a topological map through a graph

- G = (N,E)
- N = {points of interest}
- $\mathsf{E} = \{(\mathsf{p},\mathsf{q}) \mid (\mathsf{p} \in \mathsf{N}, \mathsf{q} \in \mathsf{N}, \mathsf{p} = \mathsf{q} \pm 1) \lor (\mathsf{p} \text{ and } \mathsf{q} \in \mathsf{N}, \mathsf{p} = \mathsf{q} \pm 1) \lor (\mathsf{p} \text{ and } \mathsf{q} \in \mathsf{N}, \mathsf{p} = \mathsf{q} \pm 1) \lor (\mathsf{p} \text{ and } \mathsf{q} \in \mathsf{N}, \mathsf{p} = \mathsf{q} \pm 1) \lor (\mathsf{p} \text{ and } \mathsf{q} \in \mathsf{N}, \mathsf{p} = \mathsf{q} \pm 1) \lor (\mathsf{p} \text{ and } \mathsf{q} \in \mathsf{N}, \mathsf{p} = \mathsf{q} \pm 1) \lor (\mathsf{p} \text{ and } \mathsf{q} \in \mathsf{N}, \mathsf{p} = \mathsf{q} \pm 1) \lor (\mathsf{p} \text{ and } \mathsf{q} \in \mathsf{N}, \mathsf{p} = \mathsf{q} \pm 1) \lor (\mathsf{p} \text{ and } \mathsf{q} \in \mathsf{N}, \mathsf{p} = \mathsf{q} \pm 1) \lor (\mathsf{p} \text{ and } \mathsf{q} \in \mathsf{N}, \mathsf{p} = \mathsf{q} \pm 1) \lor (\mathsf{p} \text{ and } \mathsf{q} \in \mathsf{N}, \mathsf{p} = \mathsf{q} \pm 1) \lor (\mathsf{p} \text{ and } \mathsf{q} \in \mathsf{N}, \mathsf{p} = \mathsf{q} \pm 1) \lor (\mathsf{p} \text{ and } \mathsf{q} \in \mathsf{N}, \mathsf{p} = \mathsf{q} \pm 1) \lor (\mathsf{p} \text{ and } \mathsf{q} \in \mathsf{N}, \mathsf{p} = \mathsf{q} \pm 1) \lor (\mathsf{p} \text{ and } \mathsf{q} \in \mathsf{N}, \mathsf{p} = \mathsf{q} \pm 1) \lor (\mathsf{p} \text{ and } \mathsf{q} \in \mathsf{N}, \mathsf{p} = \mathsf{q} \pm 1) \lor (\mathsf{p} \text{ and } \mathsf{q} \in \mathsf{N}, \mathsf{p} = \mathsf{q} \pm 1) \lor (\mathsf{p} \text{ and } \mathsf{q} \in \mathsf{N}, \mathsf{p} = \mathsf{q} \pm 1) \lor (\mathsf{p} \text{ and } \mathsf{q} \in \mathsf{N}, \mathsf{p} = \mathsf{q} \pm 1) \lor (\mathsf{p} \text{ and } \mathsf{q} \in \mathsf{N}, \mathsf{p} = \mathsf{q} \pm 1) \lor (\mathsf{p} \text{ and } \mathsf{q} \in \mathsf{N}, \mathsf{p} = \mathsf{q} \pm 1) \lor (\mathsf{p} \text{ and } \mathsf{q} \in \mathsf{N}, \mathsf{p} = \mathsf{q} \pm 1) \lor (\mathsf{p} \text{ and } \mathsf{q} \in \mathsf{N}, \mathsf{p} = \mathsf{q} \pm 1) \lor (\mathsf{p} \text{ and } \mathsf{q} \in \mathsf{N}, \mathsf{p} = \mathsf{q} \pm 1) \lor (\mathsf{p} \text{ and } \mathsf{q} \in \mathsf{N}, \mathsf{p} = \mathsf{q} \pm 1) \lor (\mathsf{p} \text{ and } \mathsf{q} \in \mathsf{N}, \mathsf{p} = \mathsf{q} \pm 1) \lor (\mathsf{p} \text{ and } \mathsf{q} \in \mathsf{N}, \mathsf{p} = \mathsf{q} \pm 1) \lor (\mathsf{p} \text{ and } \mathsf{q} \in \mathsf{N}, \mathsf{p} = \mathsf{q} \pm 1) \lor (\mathsf{p} \text{ and } \mathsf{q} \in \mathsf{N}, \mathsf{p} = \mathsf{q} \pm 1) \lor (\mathsf{p} \text{ and } \mathsf{q} \in \mathsf{N}, \mathsf{p} \in \mathsf{q} \in \mathsf{N}, \mathsf{p} \in \mathsf{N}, \mathsf{p} \in \mathsf{N})$

represent the same door for two different rooms}

Planning and world models

The objective of planning is to find a trajectory for the robot to reach a goal configuration, from a start configuration (its current position), avoiding obstacles

Planning and world models

 The robot size can be used to increase the obstacle size and then consider the robot as a point

Planning and world models

Planning is divided in:

- Path Planning: techniques for finding trajectories for the robot to reach the goal configuration, avoiding obstacles
- Path Following: techniques for executing the trajectories generated by the Path Planning, avoiding unexpected obstacles.

Configuration Space

- Space is named Configuration Space o C_{space} (configurations that the robot can reach).
- The robot is represented in C_{space} as a point.
- Obstacles are represented in C_{space}.
- The region of obstacles is named C_{obstacle}.
- The region of free space is named C_{free}.
- A path is a trajectory between two configurations q_{init} and q_{goal} of C_{space} belonging to C_{free}.

Path Planning and world models for geometric maps

Main Path Planning techniques based on geometric maps:

- Roadmaps
- Cell Decomposition
- Pontential Fields

Roadmaps

- The Roadmap approach consists of connecting some points of the free space in a network, named Roadmap, made of unidimensional curves in the free space.
- The Path Planning problem becomes connecting the start and the goal configurations by finding a path in the roadmap.

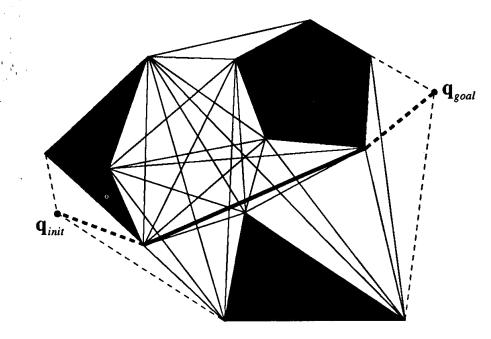

Main Path Planning techniques based on the Roadmap approach:

- Visibility Graph
- Voronoi Diagram

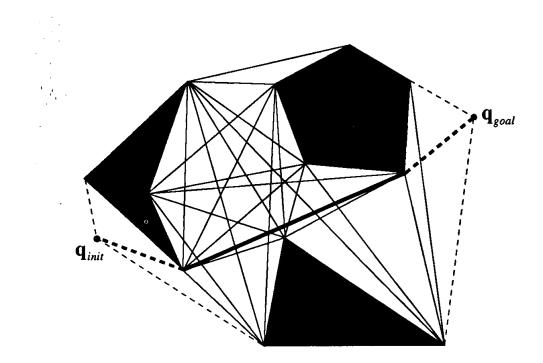

Visibility Graph

- The visibility graph is a graph G whose nodes are the initial and goal configurations, q_{init} and q_{goal}, and all vertexes of the polygons which represent the obstacles in the map
- The edges of G are all the segments that connect two nodes in G and that do not intersect the obstacle polygons
- A weight can be associated to the edges, corresponding to the distance between the nodes that they connect
- A path from q_{init} and q_{goal} can be found on the graph G by using an algorithm for minimum paths which minimizes the distance

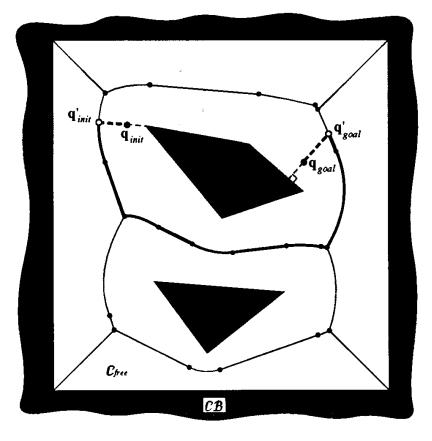

Visibility Graph

Example: visibility graph and the path found to navigate from q_{init} to q_{goal}

Voronoi Diagram

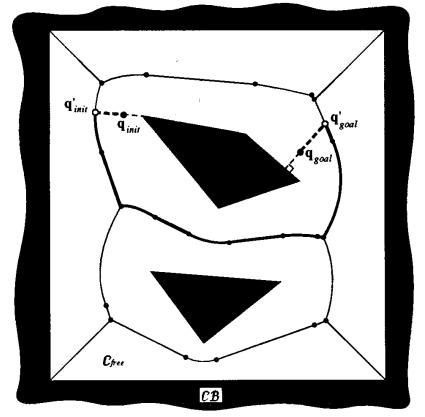

- It consists of defining all the free configurations in the free space, equidistant from the obstacle region
- If the obstacles are polygons, the Voronoi diagram consists of a finite set of segments and parabolic curves (roadmap).

Voronoi Diagram

Given two configurations q_{init} and q_{goal}, a path is given by:

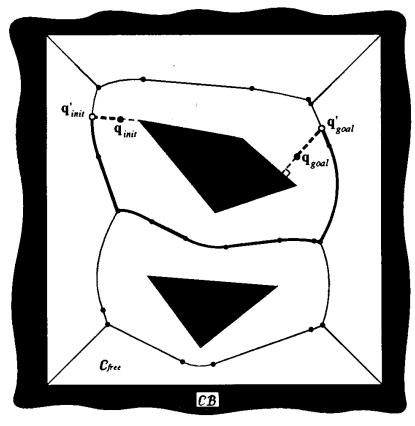

- Connecting q_{init} and q_{goal} to the roadmap in q'_{init} and q'_{goal}.
- Finding a path on the Voronoi diagram which connects q'_{init} and q'_{goal}.

Voronoi Diagram

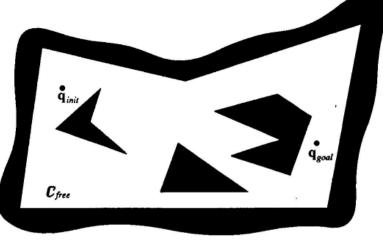

Example: Voronoi diagram and the path found to navigate from q_{init} to q_{goal}

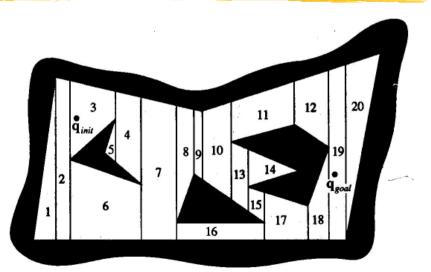

The advantage of this technique is that the trajectories tend to maximise the distance of the robot from obstacles.

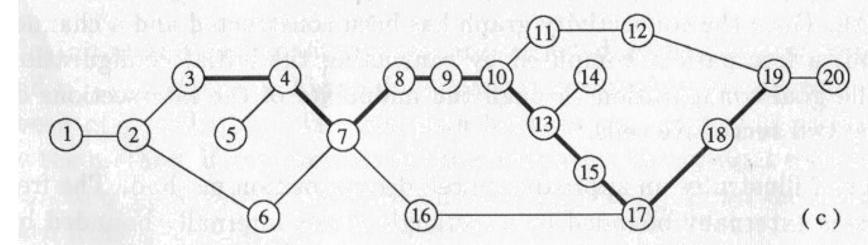

- It consists of decomposing the free space in regions, named cells, such that a path between two adjacent cells can be easily found.
- The map is represented by a graph named connectivity graph.
- The graph nodes are the cells in the free space.
- Two nodes in the graph are connected if and only if the two cells that they represent are adjacent.

Example of map and its cell decomposition

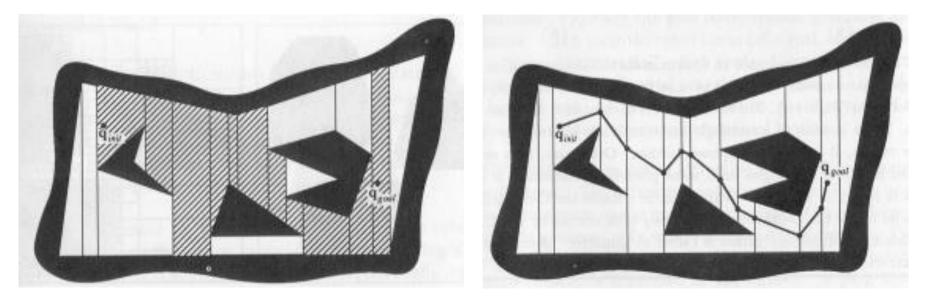

Connectivity graph associated to the map and the path found (in bold)

- A trajectory for the robot is found by searching a path on the graph that connects the nodes containing q_{init} and q_{qoal}.
- The result of the graph search is a sequence of cells named canal.
- The path is found by connecting the mid points of the canal cell boundaries.

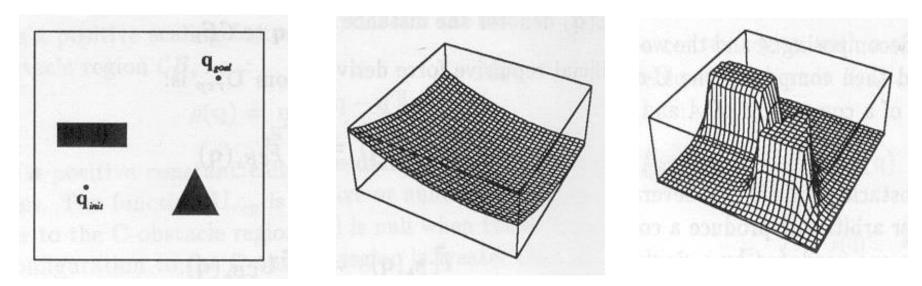

The results of the graph search are:

- The canal (grey cells)
- The path found (line in bold)

- The robot is a point in space that moves under the influence of an artificial potential produced by the goal configuration and by the obstacles
- The final configuration generates an actractive potential which pulls the robot towards the goal
- The obstacles generate a repulsive potential which pushes the robot away from them
- The sum of attractive and repulsive potentials generates a force which moves the robot towards the goal, while avoiding obstacles

Example of attractive and repulsive potential

World map

Hyperbolic attractive potential function Repulsive potential function

 Differentiable potential function U with a local minimum in the point q_{goal}

> $U(q) = U(q)_{att} + U(q)_{rep}$ $U(q)_{att}$ Attractive potential function

> $U(q)_{rep}$ Repulsive potential function

 For each point q in space, the motion direction is given by the force function F

$$F(q) = -\nabla U(q) = -(F_{att}(q) + F_{rep}(q))$$
$$\nabla U(q) = (\delta U / \delta x, \, \delta U / \, \delta y)$$

Criteria for choosing the attractive potential

Function with a local minimum in the point q_{goal}

$$U_{att}(q) = \frac{1}{2} \xi \rho^2_{goal}(q)$$
 parabolic potential where

 $\rho^2_{goal}(q) = ||q-q_{goal}||$ Euclidean distance so that

$$F_{att}(q) = -\xi (q - q_{goal})$$

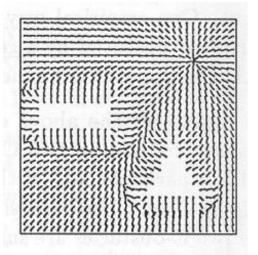

Criteria for choosing the repulsive potential

- Creating a protective barrier around the obstacle region, to avoid robot contact with the obstacles
- The repulsive force should not affect the robot motion when it is far from obstacles

$$U_{rep}(q) = \begin{cases} \frac{1}{2}\eta \left(\frac{1}{\rho(q)} - \frac{1}{\rho(q_0)}\right)^2 & \text{se } \rho(q) \le \rho_0 \\ 0 & \text{se } \rho(q) > \rho_0 \\ \end{cases}$$
where
$$\rho(q) = \min[|q-q'|] \qquad q' \in C_{obstacle}$$

q_{re}

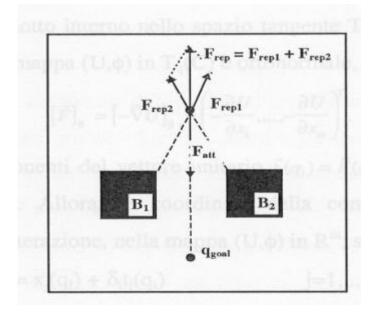

Total potential function

 $U = U_{att} + U_{rep}$

Curves of the total potential function and the trajectory found

Matrix of the gradient vector orientations

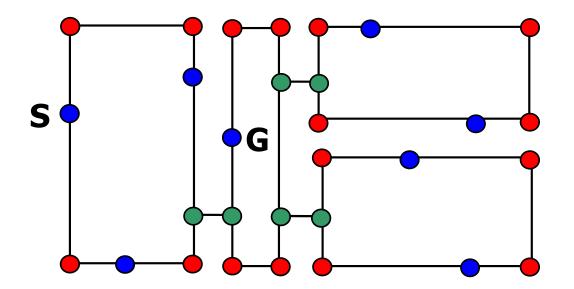

Problem of local mimina of the resulting function: they can occur when the sum of repulsive forces nullifies the attractive force in points different from q_{qoal}

Example of path on a topological map:

- Follow the wall on the right;
- Turn right;
- Follow the wall on the right;
- Stop in front of the doors;
- Enter the door and turn left
- Follow the wall on the left;
- Stop when reached the desk;

The problem of Path Planning is finding a path on the graph from the **Start** node to the **Goal** node

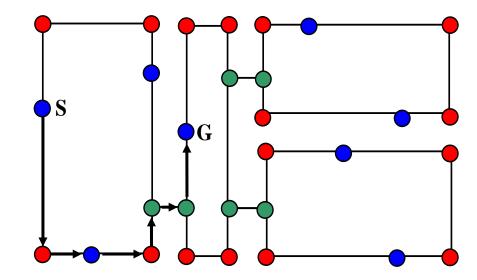

The path found is translated into commands for the robot

Rules for translating a path in a sequence of commands:

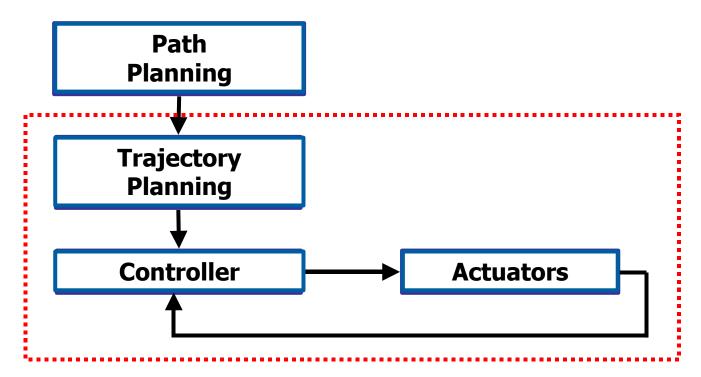

- For the Start node, the command generated is follow the wall on the right or follow the wall on the left, depending on the order of the adjacent node to reach.
- For the intermediate nodes of type Angle, the command generated is change wall on the right or change wall on the left.
- For the intermediate nodes of type **Door**, the command generated is **go straight** if the robot does not have to enter the adjacent room or **enter the door and turn left (right)** if the robot has to enter the adjacent room and it has to follow the wall on the left (right).
- For the other intermediate nodes, different from the goal node, the command is follow the wall.
- When the robot reaches the **Goal** node, the command generates is **Stop**.

Path generated for reaching the final point G starting from the initial point S:

- 1) follow the wall on the right;
- 2) change wall on the right;
- 3) follow the wall on the right;
- 4) change wall on the right;
- 5) enter the door and turn left;
- 6) follow the wall on the left;
- 7) stop when the goal point of interest is reached.

 It has the role of making the robot follow the paths generated by the Path Planner

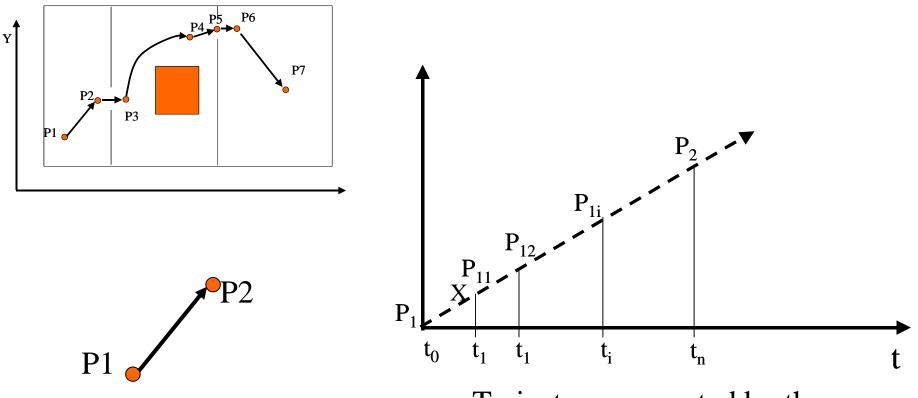

- Path planning: it finds a sequence of points in space that the robot has to reach (path)
 - $(x_1, y_1\theta_1), \dots (x_{i-1}, y_{i-1}\theta_{i-1}), (x_i, y_i\theta_i), \dots (x_n, y_n\theta_n)$
- Trajectory planning: it finds the trajectory and the time law that the robot has to follow between each couple of points (not necessarily a linear trajectory)
- Controller: it makes the robot execute the trajectory found by the trajectory planner

Path planning

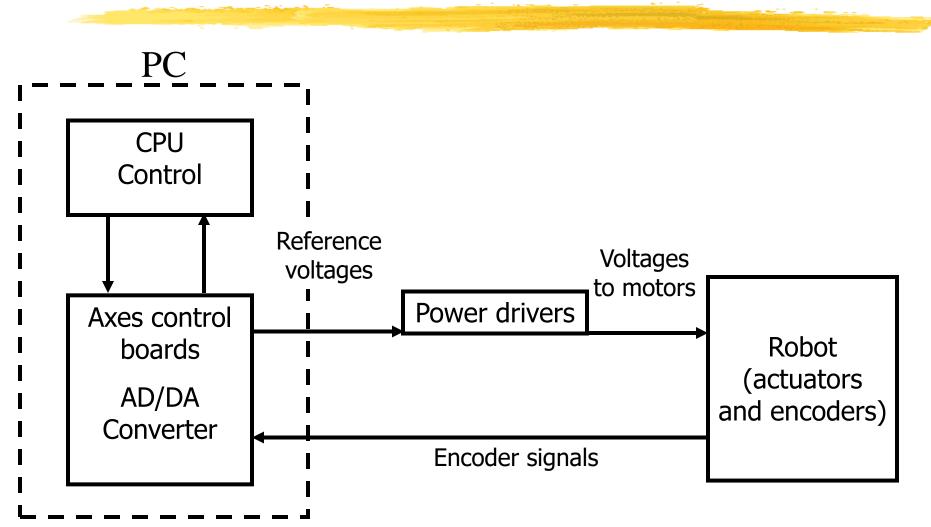

Х

Trajectory planning

Trajectory generated by the trajectory planner

Hardware architecture of a mobile robot

Controller

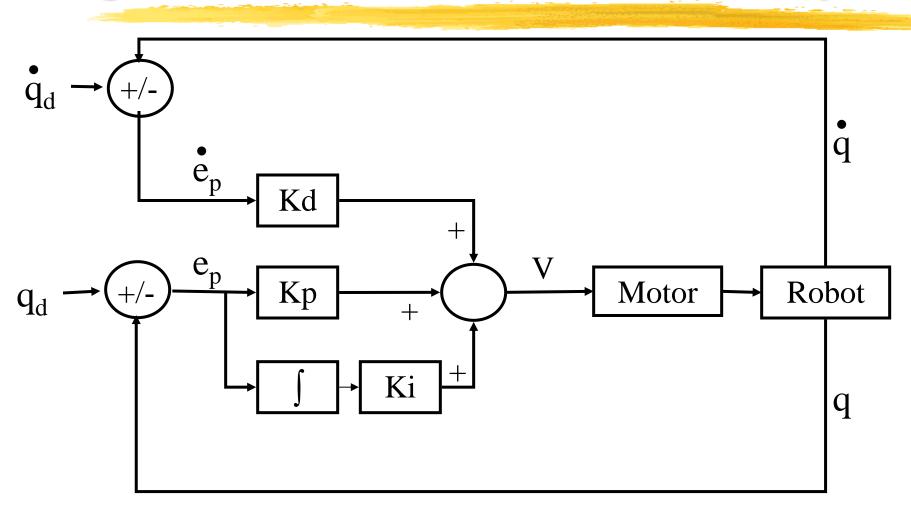

Actuator control:

Position control: it consists of setting a position to reach.

The robot controller finds the velocities and the accelerations to set to the motors for reaching the desired position (inverse kinematics).

• **Velocity control**: it consists of setting a velocity and an acceleration to the wheel motors.

Position control: Proportional, Integrative and Derivative control (PID)

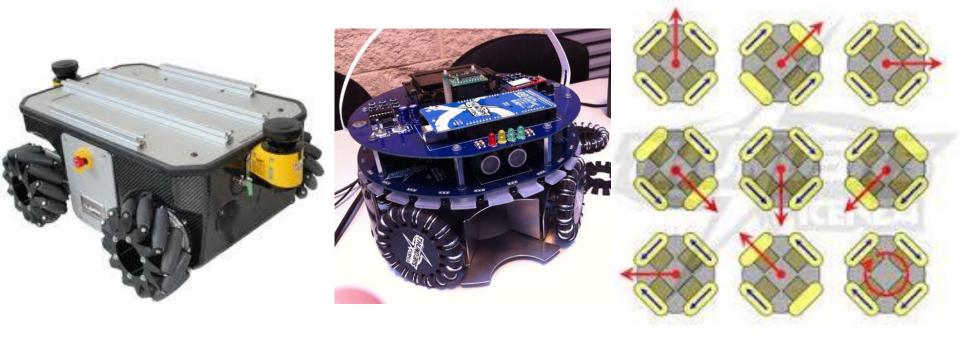

$$\mathbf{V} = \mathbf{K}_{\mathbf{p}}\mathbf{e}_{\mathbf{p}} + \mathbf{K}_{\mathbf{d}}\dot{\mathbf{e}}_{\mathbf{p}} + \mathbf{K}_{\mathbf{i}}\mathbf{J}\mathbf{e}_{\mathbf{p}}$$

- It is not always possible to follow the path planned by the Path Planner
- Problems to face:
 - Non omnidirectional mobile bases
 - Unexpected obstacles

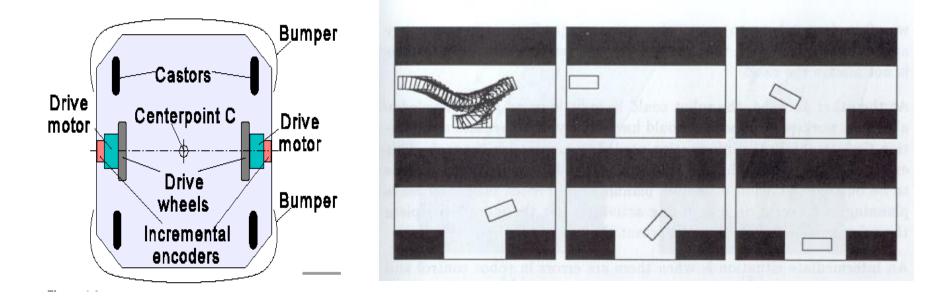

• Omnidiretional mobile base:

- Can move in any direction
- Can follow the trajectory given by the Path Planner

Non omnidiretional mobile base:

- Cannot move in any direction, due to its structure (e.g. car-like robot)
- Can not always follow the trajectory given by the Path Planner

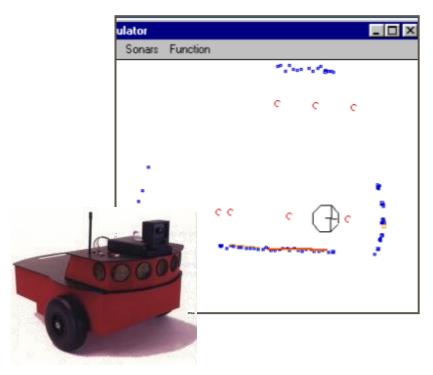

Path Following – obstacle avoidance

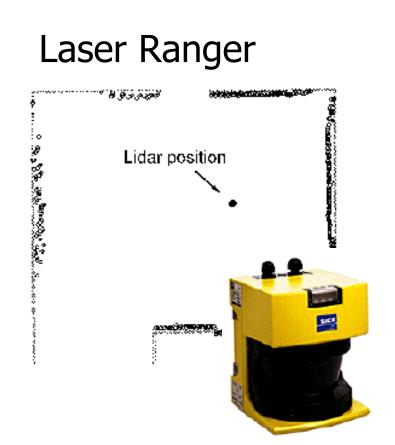

The problem of unexpected obstacles:

- unexpected obstacles are detected by the robot through ultrasound sensors or laser ranger
- the robot controller has to modify the trajectory to follow, in order to avoid obstacles
- obstacle avoidance techniques:
 - Based on occupancy grid
 - Based on potential fields

Systems for obstacle detection

Sensory systems: Ultrasound sensors

Outline of the lecture

- Fundamental problems of robot navigation
- Maps and environment models
 - Metric maps and topological maps
- Planning techniques
 - Path Planning and Path Following
- Localization methods and systems
 - Odometry and systems based on active beacons and landmarks

J.C. Latombe, *Robot Motion Planning*, Kluwer Academic Publishers, 1991

Localization

Localization methods

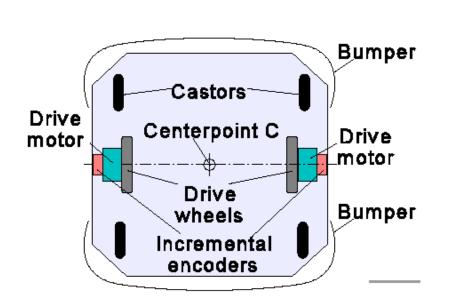

- Dead Reckoning Odometry
- Active beacons
- Natural and Artificial Landmarks

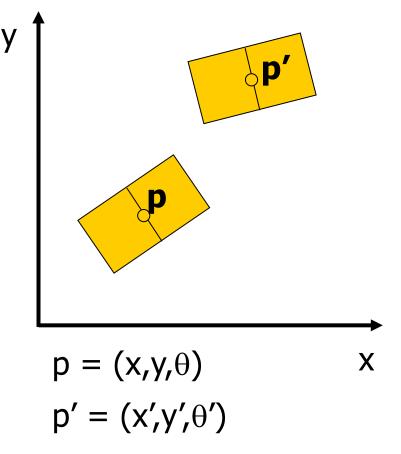

Odometry - Dead Reckoning

- It is based on counting the robot wheel turns (measured by the encoders) during navigation
- It provides a good accuracy for small movements
- The error tends to cumulate in time with the distance run (poor accuracy for long distances).
- The odometric information is rettified by using alternative localization methods.

Odometria - Dead Reckoning

Example of odometry calculation (for small movements)

Odometry - Dead Reckoning

In a time interval T, the right and left wheel encoders measure an increase of $N_L e N_R$, respectively

 $C_m = \pi D/n C_e$

where

 $\mathbf{C}_{\mathbf{m}}$ = conversion factor that translates the encoder steps in linear distance run by the wheels

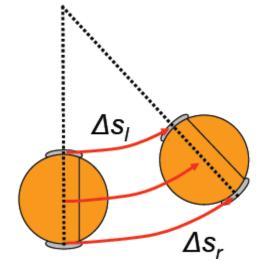

D = nominal wheel diameter

C_e = encoder resolution

n = reduction ratio between motor (where the encoder is) and wheel

Odometry – dead reckoning

Odometry - Dead Reckoning

The distance run by the right and left wheels, $\Delta S_L e \Delta S_R$, can be computed as

 $\Delta S_{I/r} = C_m N_{L/R}$

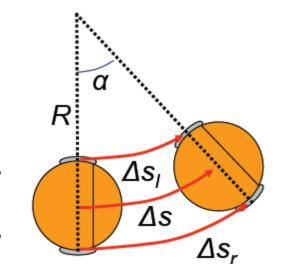

The distance run by the robot centre ΔS is:

 $\Delta S = (\Delta S_{\rm I} + \Delta S_{\rm r})/2$

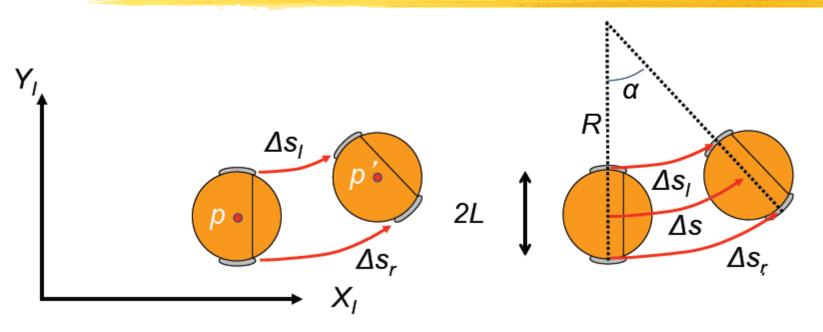

while the robot orientation angle increases of

 α = arctg ($\Delta S_r - \Delta S_l$)/2L

where 2L is the distance between the wheels (ideally measured as the distance between the points of contact of the wheels on the terrain) 2L

Odometry – dead reckoning

The new robot position p' is:

$$\theta' = \theta + \alpha$$
$$x' = x + \Delta S \cos \alpha$$
$$y' = y + \Delta S \sin \alpha$$

where (x, y, θ) was the position of the robot centre p

Odometry - Dead Reckoning

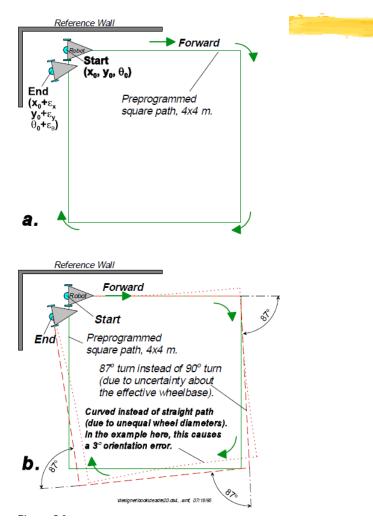

Odometric errors are of two types:

- Sistematic Errors, due to:
 - different diameters of the two wheels
 - actual size of wheels different from nominal size
 - misalignment of the wheels
 - encoder resolution

• Non sistematic errors, due to:

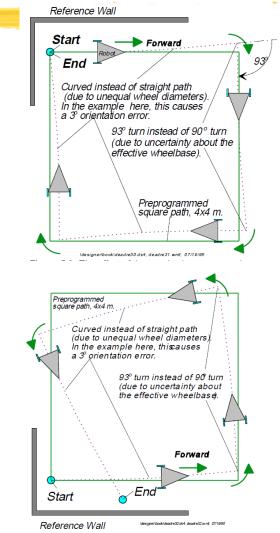

- movements on uneven terrains
- movements on unexpected objects
- wheel slippage due to
 - high accelerations
 - slipping terrains
 - external forces (obstacles)

Odometry - Dead Reckoning

The unidirectional square path experiment.

- a. The nominal path.
- b. Either one of the two significant errors E_b or E_d can cause the same final position error.

The effect of the two dominant systematic dead-reckoning errors E_b and E_d . Note how both errors may cancel each other out when the test is performed in only one direction.

The effect of the two dominant systematic odometry errors E_b and E_d : when the square path is performed in the opposite direction one may find that the errors add up.

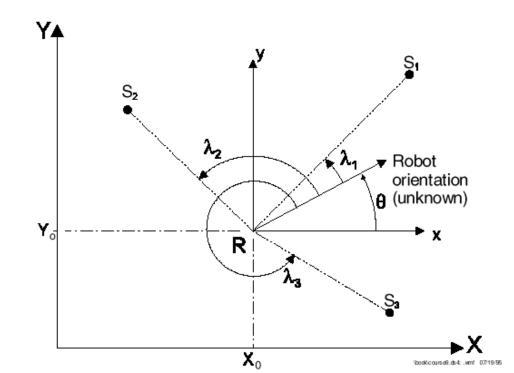

Active beacons

 Localization systems based on active beacons are composed of a set of receiver/transmitter devices (beacons) whose absolute position is known and which are detectable by a sensor on-board the robot

Active beacons

The localization algorithm is based on the triangulation procedure:

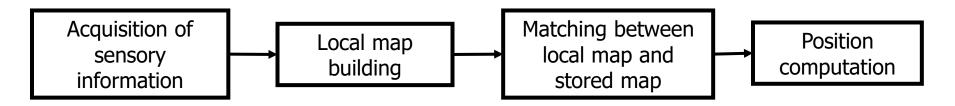

- A rotating unit on the robot can measure the angles λ_1 , λ_2 , λ_3
- By knowing the position of the 3 beacons, it is possible to derive the robot absolute position (X,Y,θ) mby triangulation

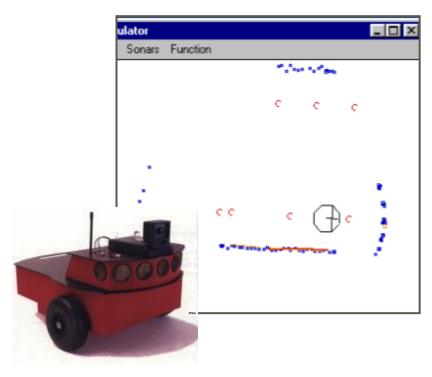

- Localization systems based on maps, or *map matching*, use one or more sensory systems for building a local map.
- The local map is compared to a global map previously stored.
- If a matching is found, the robot finds its position and orientation in space.
- A map can be a CAD model or it can be built using the robot sensory sytem.

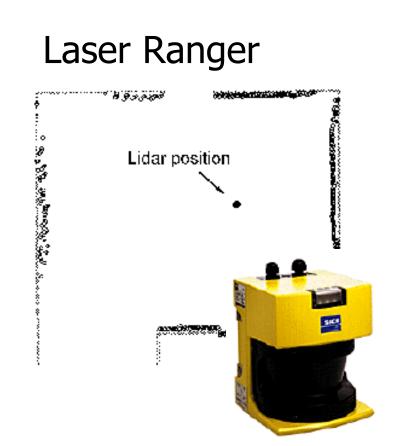

To simplify the problem, the current robot position estimated by odometry can be used.

Steps of the localization procedure:

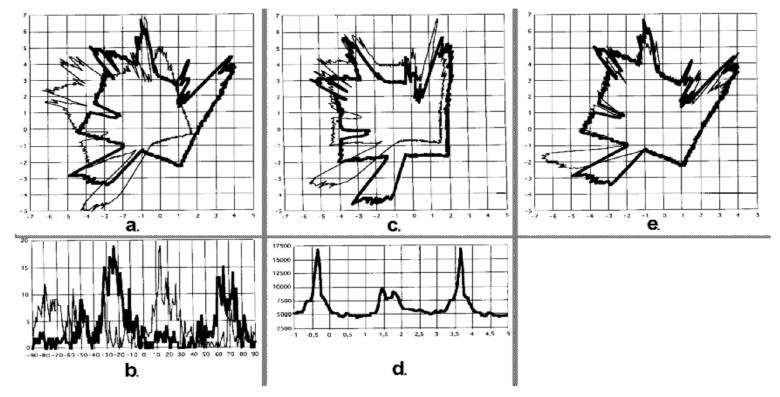

Sensory systems: Ultrasound sensors

Mapping techniques:

Correlation

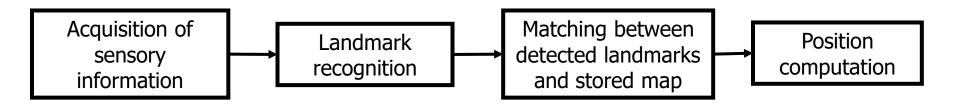

Landmarks

- Landmarks are characteristic shapes that the robot can recognize by using its sensory systems.
- Landmarks can be geometric shapes (e.g. boxes, lines, circles, ..) and they can contain additional information (e.g. bar-code).
- Landmarks are chosen so as to be easily recognised by the robot.
- The position and the characteristics of the landmarks need to be stored in the robot database.

To simplify the problem, the current robot position estimated by odometry can be used.

Steps of the localization procedure:

Landmarks

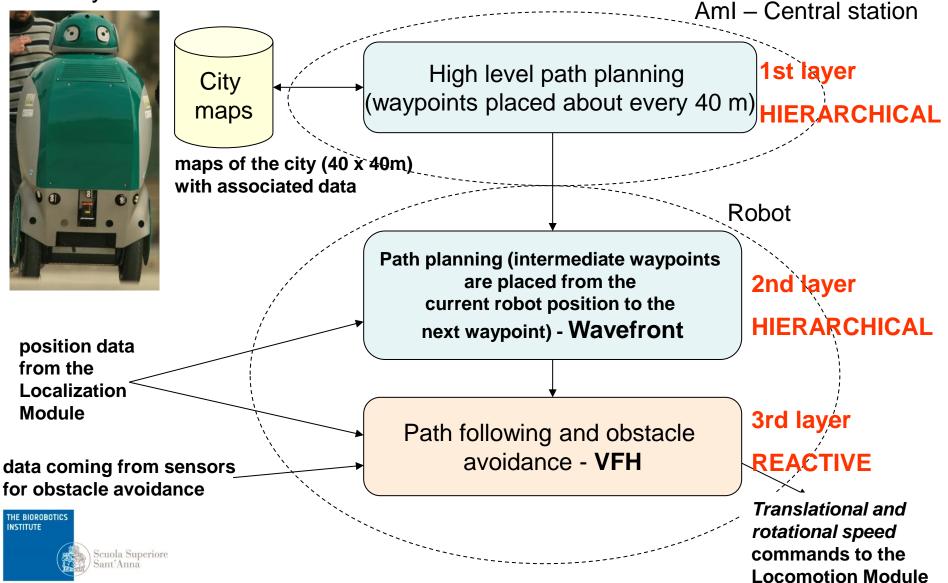

Landmarks can be divided in

- Natural Landmarks: objects already present in the environment, with specific characteristics (e.g. lights, corridors, doors, etc.).
- Artificial Landmarks: objects or markers purposively developed and placed in the environment to allow robot localization.
