File Data Access in Python

Basic functions and methods to manipulate files by default: File object

Open Method

open(file_name [, access_mode][, buffering])

Close Method

- Flushes any unwritten information and closes the file object, after which no more writing can be done
- Python automatically closes a file when the reference object of a file is reassigned to another file. Good practice to use the close() method to close a file!

Syntax: fileObject.close() Example: Example:

```
file=open("test.txt","w") with open("test.txt","w") as file
print("Name: ", file.name) print("Name: ", file.name)
file.close()
```

Open Method

3

open(file_name [, access_mode][, buffering])

- file_name: string value that contains the name of the file to be accessed
- access_mode: determines the mode in which the file has to be opened (read, write append etc.). This is optional parameter and the default file access mode is read (r)
- buffering: If the buffering value is set to 0, no buffering will take place. If the buffering value is 1, line buffering will be performed while accessing a file. If you specify the buffering value as an integer greater than 1, then buffering action will be performed with the indicated buffer size.

Open Method: Access Mode

Modes	Description
r	Opens a file for reading only. The file pointer is placed at the beginning of the file. This is the default mode.
rb	Opens a file for reading only in binary format. The file pointer is placed at the beginning of the file. This is the default mode.
r+	Opens a file for both reading and writing. The file pointer will be at the beginning of the file.
rb+	Opens a file for both reading and writing in binary format. The file pointer will be at the beginning of the file.
W	Opens a file for writing only. Overwrites the file if the file exists. If the file does not exist, creates a new file for writing.
wb	Opens a file for writing only in binary format. Overwrites the file if the file exists. If the file does not exist, creates a new file for writing.
w+	Opens a file for both writing and reading. Overwrites the existing file if the file exists. If the file does not exist, creates a new file for reading and writing.

Open Method: Access Mode

- wb+ Opens a file for both writing and reading in binary format. Overwrites the existing file if the file exists. If the file does not exist, creates a new file for reading and writing.
- a Opens a file for appending. The file pointer is at the end of the file if the file exists. That is, the file is in the append mode. If the file does not exist, it creates a new file for writing.
- ab Opens a file for appending in binary format. The file pointer is at the end of the file if the file exists. That is, the file is in the append mode. If the file does not exist, it creates a new file for writing.
- a+ Opens a file for both appending and reading. The file pointer is at the end of the file if the file exists. The file opens in the append mode. If the file does not exist, it creates a new file for reading and writing.
- ab+ Opens a file for both appending and reading in binary format. The file pointer is at the end of the file if the file exists. The file opens in the append mode. If the file does not exist, it creates a new file for reading and writing.

File Object Attributes

Attribute	Description
file.closed	Returns true if file is closed, false otherwise.
file.mode	Returns access mode with which file was opened.
file.name	Returns name of the file.
file.softspace	Returns false if space explicitly required with print, true otherwise.

Reading Files

 Read Method reads some quantity of data and returns it as a string (in text mode) or bytes object (in binary mode)

Syntax:

```
fileObject.read([size])
```

size: number of bytes to be read from the opend file. If size is missing or negative the entire file is read

Example:

```
file = open("test.txt", "r")
s = file.read()
print("The file contains: ", s)
file.close()
```

Reading Files

Loop over the file object to read lines:

for line in file:
 print(line)

Read all lines of a file in a list fileObject.readlines()

Example:

file = open("test.txt", "r")
lines = file.readlines();
file.close()

Writing Files

- Write Method writes the contents of string to the file, returning the number of characters written.
 - The write() method does not add a newline character ('\n') to the end of the string

Syntax:

```
fileObject.write(string)
```

Example:

```
file = open("test.txt", "w")
file.write("Python is a great language.\r\nYeah its
   great!!\r\n");
file.close()
```

Exercises on files

Exercise 1: RowCount.py

- Read the CSV file census_selected_header.csv
- 🗴 Return:
 - The number of rows in the file
 - The minimum number of columns
 - The maximum number of columns

Exercise 2: Select.py

- Read the CSV file census_selected_header.csv
- Write in a CSV file census_cols.csv only the list of columns passed as input
- **EX.** of parameters:
 - census_selected_header.csv census_cols.csv 3 6
 8

Columns to be reported in the output file

Getopt - Command Line Option Parsing

This function parses the argument sys.argv and returns a sequence of tuples containing (option, argument) pairs and a sequence of non-option arguments.

import getopt

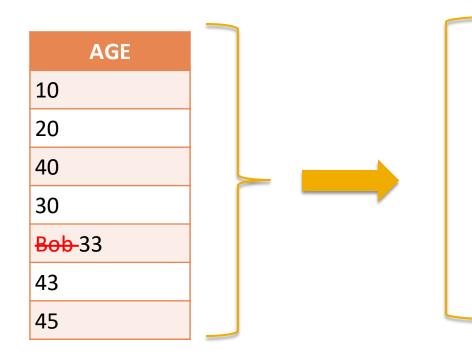

- opts,args=getopt.getopt(sys.argv[1:],"i:o:")
- for opt in opts:
 - print(opt)
- sequence of arguments to be parsed, usually coming from sys.argv[1:] (ignoring the program name in sys.arg[0])
- 2. option definition string for single character options. If one of the options requires an argument, its letter is followed by a colon.

Exercise: format conversions

 Write a Python program for converting a CSV file into the ARFF format

solve the exercises without using any additional package

Variations
 ARFE to CSV

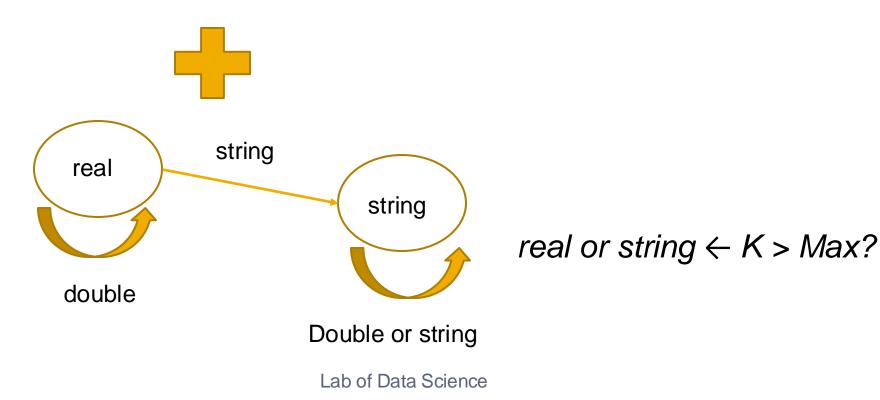

@relation
@attribute age string numeric

CSV2ARFF - solution

{ value1, value2, ..., valueK } Set of values seen so far

enumerated $\leftarrow K \le Max$?

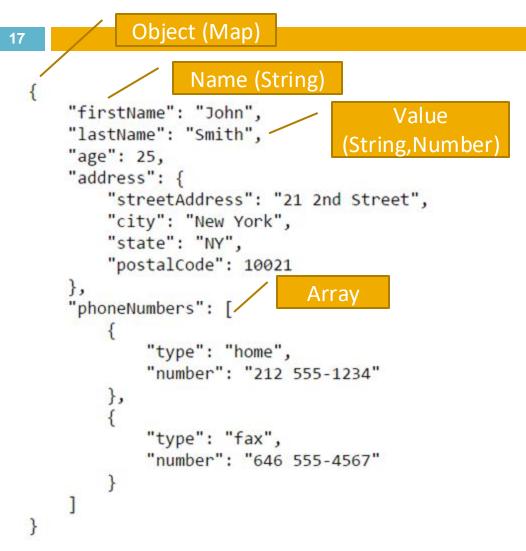

XML File Data Access in Python

- Several interfaces for working with the Extensible Markup Language (XML)
- They are grouped in the xml package:
 - https://docs.python.org/2/library/xml.html
- The XML handling submodules are:
 - xml.etree.ElementTree: the ElementTree API, a simple and lightweight XML processor https://docs.python.org/2/library/xml.etree.elementtree.html#mod ule-xml.etree.ElementTree
 - **xml.dom:** the DOM API definition
 - **xml.dom.minidom:** a minimal DOM implementation
 - **xml.dom.pulldom**: support for building partial DOM trees
 - xml.sax: SAX2 (Simple API XML) base classes and convenience functions
 - xml.parsers.expat: the Expat parser binding

Exercise(s): format conversions

- Write a Python program for converting a CSV file into the ARFF format
- Write a Python program for converting a XMLelements file into a CSV file using a DOM parser
- Write a Python program for converting a CSV file into the JSON format
 - Assume that CSV files have a first row of metadata with the names of the columns

JSON File Data Access

Exercise(s): format conversions (3)

- Write a Python program for converting a CSV file into the ARFF format
- Write a Python program for converting a XMLelements file into a CSV file using a DOM parser
- Write a Python program for converting a CSV file into the JSON format
 - Assume that CSV files have a first row of metadata with the names of the columns
