Master Program in Data Science and Business Informatics Statistics for Data Science Lesson 23 - Statistical decision theory

## Salvatore Ruggieri

Department of Computer Science University of Pisa, Italy salvatore.ruggieri@unipi.it Question: which hypothesis is the most probable given the observed data?

• Maximum Likelihood Estimation (MLE) is a frequentist method:

$$heta_{MLE} = \arg \max_{\theta} P(X_1 = x_1, \dots, X_n = x_n | \theta) = \arg \max_{\theta} \prod_{i=1}^n f_{\theta}(x_i)$$

• Maximum a Posteriori (MAP) is a Bayesian method (requires prior distribution of  $\theta$ ):

$$\theta_{MAP} = \arg \max_{\theta} P(\theta | X_1 = x_1, \dots, X_n = x_n) = \arg \max_{\theta} P(X_1 = x_1, \dots, X_n = x_n | \theta) P(\theta)$$

since by the Bayes theorem

$$P(\theta|X_1=x_1,\ldots,X_n=x_n)=\frac{P(X_1=x_1,\ldots,X_n=x_n|\theta)P(\theta)}{P(X_1=x_1,\ldots,X_n=x_n)}$$

and  $P(X_1 = x_1, \ldots, X_n = x_n)$  does not depend on  $\theta$ .

• MAP = MLE if prior is uniform

# The classification/concept learning problem

- X = (W, C) where W are predictive features and C class, with  $support(C) = \{0, 1, \dots, n_C 1\}$
- $x_1, \ldots, x_n$  are observations (training set), with  $x_i = (w_i, c_i)$  for  $i = 1, \ldots, n$
- $\theta \in \Theta$  with  $\Theta$  hypothesis space (parameters of ML model) with  $f_{\theta}$  joint density of W, C

Classification/concept learning: which hypothesis is the most probable given the observed data?

• 
$$\theta_{MLE} = \arg \max_{\theta} \ell(\theta) = \arg \min_{\theta} -\ell(\theta) = \arg \min_{\theta} \sum_{i=1}^{n} -\log f_{\theta}(x_i)$$

• 
$$f_{\theta}(x_i) = f_{\theta}(w_i, c_i) = f_{\theta}(c_i|w_i)f_{\theta}(w_i)$$

- $\bullet \ \theta_{MLE} = \arg\min_{\theta} \sum_{i=1}^{n} -\log f_{\theta}(c_i|w_i) \sum_{i=1}^{n} \log f_{\theta}(w_i)$
- Assuming  $\theta \perp W$ , we have  $f_{\theta_1}(w_i) = f_{\theta_2}(w_i)$ , and then:

$$\theta_{MLE} = \arg \min_{\theta} \sum_{i=1}^{n} -\log f_{\theta}(c_i|w_i)$$

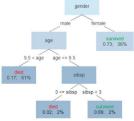

- ▶ How to compute  $\theta_{MLE}$ ? Closed form, brute force enumeration of  $\theta \in \Theta$ , heuristic search, ...
- $f_{\theta}(c|w) = P(C = c|W = w, \theta)$  is called a **probabilistic classifier** learned/trained from  $x_1, \ldots, x_n$

# Probabilistic classifiers: examples

- Logistic regression
- k-Nearest Neighbors (k-NN)
- Decision trees
- Neural networks
- Naive Bayes  $P(C = c_0 | W = w) = P(C = c_0) \prod_i P(W_i = w_i | C = c_0) / P(W = w)$ assuming  $P(W = w | C = c_0) = \prod_i P(W_i = w_i | C = c_0)$

Survival of passengers on the Titanic

- Ensembles
- Gradient boosting
- . . .
- More classifiers at the Data Mining course

# MLE and KL divergence/Cross-Entropy

$$heta_{MLE} = rg \min_{ heta} \sum_{i=1}^n -\log f_ heta(c_i|w_i)$$

- Assume data is generated from  $f_{ heta_{TRUE}}$ , i.e.,  $(W, C) \sim f_{ heta_{TRUE}}$
- We compute:

$$\theta_{MLE} = \arg\min_{\theta} \sum_{i=1}^{n} (-\log f_{\theta}(c_{i}|w_{i}) + \log f_{\theta_{TRUE}}(c_{i}|w_{i})) = \arg\min_{\theta} \frac{1}{n} \sum_{i=1}^{n} \log \frac{f_{\theta_{TRUE}}(c_{i}|w_{i})}{f_{\theta}(c_{i}|w_{i})}$$

$$\xrightarrow{n \to \infty}_{LLN} \arg\min_{\theta} E_{(W,C) \sim f_{\theta_{TRUE}}} [\log \frac{f_{\theta_{TRUE}}(C|W)}{f_{\theta}(C|W)}] = \arg\min_{\theta} D(\theta_{TRUE} \parallel \theta) = \arg\min_{\theta} H(\theta_{TRUE}; \theta)$$
[See Lesson 11 for D() and H(), and the bottom of the R Script in Lesson 19]

• Asymptotically: ML maximization = KL divergence minimization = Cross-entropy minimization

# The classification/concept prediction problem

**Question:** which is the most probable class value given w and  $\theta$ ? Written  $y_{\theta}(w) = \dots$ 

• **Problem**: given  $\theta \in \Theta$  and W = w, what is the most probable C = c? i.e.:

$$\mathop{arg}\max_{c} P(C=c,W=w| heta)$$

which is equivalent, assuming  $\theta \perp\!\!\!\perp W$ , to:

$$arg \max_{c} P(C = c | W = w, \theta) \cdot P(W = w | \theta) = arg \max_{c} f_{\theta}(c | w)$$

• Bayes decision rule 
$$y^*_{ heta}(w) = arg \max_c f_{ heta}(c|w)$$

[or simply,  $y^*$ ]

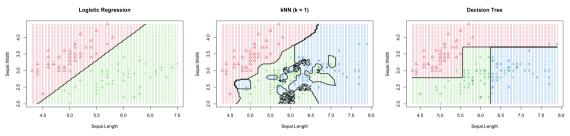

#### Theorem (Bayes decision rule is optimal)

Fix  $\theta \in \Theta$ . For any decision rule  $y_{\theta}^+ : \mathbb{R}^{|W|} \to \{0, \dots, n_C - 1\}$ :

 $P(y^*_{ heta}(W) \neq C) \leq P(y^+_{ heta}(W) \neq C)$ 

**Proof.** 
$$P(y_{\theta}^{*}(W) = C) = E[\mathbb{1}_{y_{\theta}^{*}(W) = C}] = E[E_{C}[\mathbb{1}_{y_{\theta}^{*}(W) = C}|W = w]] \ge$$
  
 $\ge E[E_{C}[\mathbb{1}_{y_{\theta}^{+}(W) = C}|W = w]] = E[\mathbb{1}_{y_{\theta}^{+}(W) = C}] = P(y_{\theta}^{+}(W) = C)$ 

# Decision boundary

- A decision boundary for a decision rule  $y_{\theta}^+()$  is the region  $w \in \mathbb{R}^{|W|}$  such that  $y_{\theta}^+(w)$  could admit as possible answers two or more classes
- For  $y_{\theta}^*$ , it is the region  $w \in \mathbb{R}^{|W|}$  such that  $\arg \max_c f_{\theta}(c|w)$  is not unique.
- For  $y^*_{\theta}$  and  $n_C = 2$ , it is the region  $w \in \mathbb{R}^{|W|}$  such that  $f_{\theta}(1|w) = 0.5$ .

#### See R script

# Bayes optimal predictions

Question: which is the most probable class value given w only (i.e., without fixing the parameters)?

- Possible answer: the prediction of the most probable model, i.e.,  $arg \max_{c} P(C = c | W = w, \theta_{MAP})$
- No, we can do better
  - Let  $\Theta = \{\theta_1, \theta_2, \theta_3\}$  and  $\Box P(\theta_1 | X_1 = x_1, \dots, X_n = x_n) = 0.4$  $\Box P(\theta_2 | X_1 = x_1, \dots, X_n = x_n) = P(\theta_3 | X_1 = x_1, \dots, X_n = x_n) = 0.3$
  - Hence  $\theta_{MAP} = \theta_1$
  - Assume  $f_{ heta_1}(1|w) = 1$  and  $f_{ heta_2}(0|w) = f_{ heta_3}(0|w) = 1$
  - Hence, class 0 has the largest probability (over the hypothesis space), whilst  $\theta_{MAP}$  predicts 1
- **Problem**: given W = w, what is the most probable C = c? i.e.:

$$\arg \max_{c} P(C = c | W = w, X_1 = x_1, \dots, X_n = x_n)$$

#### Bayes optimal prediction

arg 
$$\max_{c} \sum_{\theta \in \Theta} f_{\theta}(c|w) P(\theta|X_1 = x_1, \dots, X_n = x_n)$$

# No-Free-Lunch theorem

• A learner A is a computable function that maps a training set  $x_1, \ldots, x_n$  into a decision rule  $y_{\theta}()$ 

Question: Is there a learner  $\mathcal A$  that always maps a training set into a decision rule with zero error?

#### No-Free-Lunch theorem (Molpert, 1996)

Consider binary classification, i.e.,  $n_C = 2$ , and a finite domain  $dom(W) < \infty$ . For any learner A, there exists a distribution F with  $(W, C) \sim F$  such that:

For at least 1/7 of the training sets x<sub>1</sub>,..., x<sub>n</sub> (realizations of F<sup>n</sup>) with n < |dom(W)|/2, the decision rule y<sup>+</sup><sub>θ</sub> in output by A has an error of at least 1/8, i.e.:

 $P_F(y^+_{ heta}(W) 
eq C) \geq 1/8$ 

▶ and there exists an error-free decision rule  $y_{\theta}^{\star}$  s.t.  $P_F(y_{\theta}^{\star}(W) \neq C) = 0$ .

See here for an accessible proof

- A universal learner does no exist! No learner can succeed on all learning tasks: every learner has tasks on which it fails whereas other learners succeed.
- The learnt y<sup>+</sup><sub>θ</sub> is likely to have a large error for F, whereas there exists another learner that will output a decision rule y<sup>\*</sup><sub>θ</sub> with no error.

## Probabilistic classifiers

- Probabilistic classifier:  $f_{\theta}(c|w) \in [0,1]$  with  $\sum_{c} f_{\theta}(c|w) = 1$ :
  - learned from  $x_1, \ldots, x_n$
  - ▶ predicted probabilities  $(p_0, ..., p_{n_c-1})$  with  $p_i = f_{\theta}(i|w)$
  - most probable class  $y^*_{ heta} = arg \max_c f_{ heta}(c|w)$
  - ▶ confidence (of most probable class)  $p_{\theta}^* = \max_c f_{\theta}(c|w)$
- Unnormalized classifier:  $uc_{ heta}(c|w) \in \mathbb{R}$ 
  - unnormalized values  $(v_0, \ldots, v_{n_c-1})$  with  $v_i = uc_{\theta}(i|w)$
  - normalization using softmax:

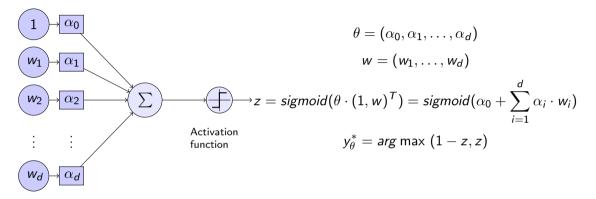

$$softmax((v_0, ..., v_{n_c-1})) = (\frac{e^{v_0}}{\sum_i e^{v_i}}, ..., \frac{e^{v_{n_c-1}}}{\sum_i e^{v_i}})$$

• binary classes ( $v_0 = 0, v_1$ ):

 $softmax((0, v_1)) = (1 - z, z)$  where  $z = sigmoid(v_1) = inv.logit(v_1) = \frac{1}{1 + e^{-v_1}}$ 

- $softmax(\mathbf{v} + c) = softmax(\mathbf{v})$
- $\frac{d}{d\mathbf{v}}$ softmax( $\mathbf{v}$ ) = softmax( $\mathbf{v}$ )(1 softmax( $\mathbf{v}$ ))

# Example: Perceptron with sigmoid activation

inputs weights

- Difference with logistic regression?
  - Weights calculated differently (MLE vs gradient descent)
  - Perceptron is parametric to activation functions
  - Perceptron with sigmoid activation = Logistic regression

# Binary classification/concept learning

- X = (W, C) where W are predictive features and C class, with  $support(C) = \{0, 1\}$
- $x_1, \ldots, x_n$  are observations (training set), with  $x_i = (w_i, c_i)$
- **Definition.** Score function:  $s_{\theta}(w) = f_{\theta}(1|w) = P(C = 1|W = w, \theta)$ 
  - predicted probabilities  $(1 s_{\theta}(w), s_{\theta}(w))$
  - confidence (of most probable class):  $\max\{1 s_{\theta}(w), s_{\theta}(w)\}$

$$f_{\theta}(c_i|w_i) = s_{\theta}(w_i)^{c_i}(1-s_{\theta}(w_i))^{(1-s_i)}$$

• MLE estimation

$$heta_{MLE} = rg\min_{ heta}\sum_{i=1}^n -\log f_ heta(c_i|w_i) = rg\min_{ heta}rac{1}{n}\sum_{i=1}^n -c_i\log s_ heta(w_i) - (1-c_i)\log\left(1-s_ heta(w_i)
ight)$$

• Cross-entropy loss or log-loss:

$$\ell_{\theta}(c, w) = \begin{cases} -\log s_{\theta}(w) & \text{if } c = 1\\ -\log (1 - s_{\theta}(w)) & \text{if } c = 0 \end{cases}$$

• MLE maximization = Log-loss minimization

$$\theta_{MLE} = \arg\min_{\theta} \frac{1}{n} \sum_{i=1}^{n} \ell_{\theta}(c_i, w_i)$$

....

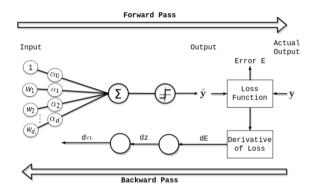

# MLE and ERM for classification/concept learning

#### Empirical risk minimization

Let  $\ell_{\theta} : \{0, \dots, n_{C} - 1\} \times \mathbb{R}^{|W|} \to \mathbb{R}_{\geq 0}$  be a loss function.  $\theta_{ERM} = \arg \min_{\theta} \frac{1}{n} \sum_{i=1}^{n} \ell_{\theta}(c_{i}, w_{i})$ 

- MLE is ERM with Log-loss  $\ell_{ heta}(c,w) = -\log f_{ heta}(c|w) = \log rac{1}{P(c|w, heta)}$
- 0-1 loss  $\ell_{\theta}(c, w) = \mathbb{1}_{y_{\theta}^+(w) \neq c}$  where  $y_{\theta}^+(w) \in \{0, \dots, n_C 1\}$  is a decision rule
  - ▶ not convex, not differentiable, optimization problem is NP-hard
- $L_p$  error loss for binary classifiers  $\ell_ heta(c,w) = |s_ heta(w) c|^p$ 
  - absolute error loss or  $L_1$ :  $|s_{\theta}(w) c|$
  - squared error loss or  $L_2$  or Brier score:  $(s_{\theta}(w) c)^2$

# Loss functions and classifiers

- Gradient of loss function determines updates of weights α<sub>0</sub>,..., α<sub>d</sub> in the direction of improving the loss (Backpropagation)
- Similar idea in ensemble of decision trees, where each one improves on the error of the previous one (Gradient boosting trees)

# MSE and the bias-variance trade-off

• Squared error loss  $\theta_{ERM} = arg \min_{\theta} MSE$ , where the Mean Squared Error is:

$$MSE = rac{1}{n}\sum_{i=1}^n (s_ heta(w_i) - c_i)^2$$

- ► Why named *MSE*? Because *MSE*  $\xrightarrow{n \to \infty}_{LLN} E_{(W,C) \sim f_{\theta_{TRUE}}}[(s_{\theta}(W) C)^2]$
- MSE approximates the Mean Squared-Error over the population
- ▶ Notice: in MSE for estimators *C* was a constant (parameter)
- Assumes that  $C = D + \epsilon$ , where  $E[\epsilon] = 0$ 
  - Observed class labels  $c_i$  include some noise w.r.t. true labels, i.e.,  $c_i = d_i + \epsilon_i$
- Decomposition of MSE:

$$E_{(W,C)\sim f_{\theta_{TRUE}}}[(s_{\theta}(W)-C)^2] = Var(s_{\theta}(W)) + E[s_{\theta}(W)-C]^2 + Var(\epsilon)$$

- $Var(\epsilon)$  irreducible error (would require better curated class values in the training set)
- ►  $E[s_{\theta}(W) C]^2$  is Bias<sup>2</sup>. Minimized by interpolating training data, but with high variance.
- $Var(s_{\theta}(W))$  variance of the scores. Minimized by a constant score, but with high bias.

#### See R script

[See Lesson 18]

# Loss functions and risk

Squared error loss minimization on training set generalizes to the population:

$$\theta_{ERM} = \arg\min_{\theta} \frac{1}{n} \sum_{i=1}^{n} (s_{\theta}(w) - c_i)^2 \xrightarrow{n \to \infty}_{LLN} \arg\min_{\theta} E_{(W,C) \sim f_{\theta_{TRUE}}}[(s_{\theta}(W) - C)^2]$$

### Risk (or Expected Prediction Error EPE)

The risk w.r.t. a loss function  $\ell_{\theta}$  is  $R(\theta_{TRUE}, \theta) = E_{(W,C) \sim f_{\theta_{TRUE}}}[\ell_{\theta}(C, W)].$ 

Definition. A loss function is a proper scoring rule if:

$$\theta_{TRUE} = \arg\min_{\theta} R(\theta_{TRUE}, \theta)$$

- For log-loss,  $R(\theta_{TRUE}, \theta) = D(\theta_{TRUE} \parallel \theta) \ge 0$  and  $D(\theta_{TRUE} \parallel \theta) = 0$  iff  $\theta = \theta_{TRUE}$
- Log-loss, squared error  $(L_2)$  and 0-1 loss are proper scoring rules, whilst  $L_1$  is not
  - For proper scoring rules,  $\theta_{ERM} \xrightarrow{n \to \infty} \theta_{TRUE}$  (recall we assume such  $(W, C) \sim f_{\theta_{TRUE}}$ ) exists
  - Still, 0-1 loss is discontinuous and can be harmful!

## Best classifier for 0-1 loss

**Question:** what is the decision rule with the smallest 0-1 risk? I.e.,  $\arg \min_{y_a^+} E_{(W,C) \sim f_{\theta_{TRUE}}}[\mathbb{1}_{y_a^+(W) \neq C}]?$ 

Binary class Bayes optimal classifier (or Bayes rule):

$$y^*_{ heta_{TRUE}}(w) = \left\{egin{array}{cc} 1 & ext{if } \eta(w) \geq 1/2 \ 0 & ext{if } \eta(w) < 1/2 \end{array}
ight.$$

where  $\eta(w) = P_{\theta_{TRUE}}(C = 1 | W = w)$ .

$$\begin{split} E_{(W,C)\sim f_{\theta_{TRUE}}}[\mathbb{1}_{y_{\theta}^{+}(W)\neq C}] &= E_{W}[E_{C}[\mathbb{1}_{y_{\theta}^{+}(W)\neq C}|W]] \\ &= E_{W}[P(C=1|W) \cdot \mathbb{1}_{y_{\theta}^{+}(W)\neq 1} + P(C=0|W) \cdot \mathbb{1}_{y_{\theta}^{+}(W)\neq 0}] \\ &= E_{W}[\eta(W) \cdot \mathbb{1}_{y_{\theta}^{+}(W)=0} + (1-\eta(W)) \cdot \mathbb{1}_{y_{\theta}^{+}(W)=1}] \\ &\geq E_{W}[\min\{\eta(W), 1-\eta(W)\}] \\ &= E_{W}[\eta(W) \cdot \mathbb{1}_{y_{\theta_{TRUE}}^{*}(W)=0} + (1-\eta(W)) \cdot \mathbb{1}_{y_{\theta_{TRUE}}^{*}(W)=1}] \\ &= E_{(W,C)\sim f_{\theta_{TRUE}}}[\mathbb{1}_{y_{\theta_{TRUE}}^{*}(W)\neq C}] & \text{Bayes error rate} \\ & \text{See R script} \end{split}$$

# Bayes optimal classifier

$$\eta(w) = P_{\theta_{TRUE}}(C = 1 | W = w)$$

•  $\eta()$  is unknown! (unless we are controlling data generation)

- Plug-in rule: use  $\hat{\eta}(w) = f_{\theta}(c|w) = P_{\theta}(C = 1|W = w)$  as an estimate of  $\eta(w)$
- Naive Bayes  $P(C = c_0 | W = w) = P(C = c_0) \prod_i P(W_i = w_i | C = c_0) / P(W = w)$ assuming  $P(W = w | C = c_0) = \prod_i P(W_i = w_i | C = c_0)$ 
  - ▶ Naive Bayes estimates  $\eta(w)$  from empirical distribution of  $x_1, \ldots, x_n$
  - and assuming independence of features
- 1-NN asymptotically converges  $(|\theta| \rightarrow \infty)$  to risk: [Cover and Hart (1967)]

$$r \leq E_{(W,C) \sim f_{\theta_{TRUE}}}[\mathbb{1}_{y_{\theta}^{1-NN}(W) \neq C}] \leq 2r(1-r) \leq 2r$$

where r is the Bayes error rate.

- Bayes optimal classifier is optimal also for squared loss
  - Squared loss is convex and differentiable (better use for optimization)

[Prove it]

## Maximum and Bayes risks

### Risk (or Expected Prediction Error EPE)

The risk w.r.t. a loss function  $\ell_{\theta}$  is  $R(\theta_{TRUE}, \theta) = E_{(W,C) \sim f_{\theta_{TRUE}}}[\ell_{\theta}(C, W)].$ 

Risk is defined w.r.t. a specific  $\theta_{TRUE}$ . What is the maximum risk at the variation of  $\theta_{TRUE}$ ? **Definition.** The maximum risk is

$$ar{R}( heta) = \sup_{ heta_{TRUE}} R( heta_{TRUE}, heta)$$

A classifier  $f_{\theta'}$  such that  $\bar{R}(\theta') = \inf_{\theta} \bar{R}(\theta)$  is called a **minimax rule**. **Definition.** Let  $f(\theta_{TRUE})$  be a prior for  $\theta_{TRUE}$ . The Bayes risk is

$$r(\theta) = \int R(\theta_{TRUE}, \theta) f(\theta_{TRUE}) d\theta_{TRUE}$$

A classifier  $f_{\theta'}$  such that  $r(\theta') = \inf_{\theta} r(\theta)$  is called a **Bayes rule**.

# Loss functions and margin

- Binary classes  $C = \{-1, 1\}$ , unnormalized scores  $s_{ heta}(w) \in \mathbb{R}$ 
  - Bayes decision rule becomes:  $y_{\theta}^* = sgn(s_{\theta}(w))$
- Margin for (w, c) defined as

$$m = c \cdot s_{\theta}(w)$$

- Margin > 0 if prediction is correct (i..e,  $s_{\theta}(w) \ge 0$  and c = 1, or if  $s_{\theta}(w) < 0$  and c = -1)
- Loss minimization equivalent to margin maximization
- Margin-based loss: Loss function  $\ell_{\theta}(c, w)$  that can be written as  $\phi(m)$ :
  - ▶ 0-1 loss:  $\phi(m) = \mathbb{1}_{m \leq 0}$
  - Logistic log-loss:  $\phi(m) = \log_2 (1 + e^{-m})$
  - $L_2$  loss:  $\phi(m) = (1-m)^2$
  - SVM/Hinge loss:  $\phi(m) = \max\{0, 1 m\}$
  - AdaBoost/Exponential loss:  $\phi(m) = e^{-m}$
- Methods for margin maximization exists for a convex margin-based loss
  - that also provide bounds on 0-1 loss
  - that encode regularizations in the margin-based loss

#### See R script

#### See R script

. . .

$$\eta(w) = P_{\theta_{TRUE}}(C = 1 | W = w)$$

Bayes optimal classifier (or Bayes rule):

$$y^*_{ heta_{TRUE}}(w) = \left\{egin{array}{cc} 1 & ext{if } \eta(w) \geq 1/2 \ 0 & ext{if } \eta(w) < 1/2 \end{array}
ight.$$

- If  $\eta(w) pprox 1/2$ , we might just as well toss a coin to make a decision
- This motivates the introduction of a reject option for classifiers
  - ▶ reject, or abstain, expressing doubt or uncertainty in decisions
  - ▶ relevant in practice (e.g., to understand the cases where a classifier performs poorly),
  - relevant ethically for socially sensitive decision tasks (e.g., credit scoring, disease prediction, CV screeening, etc.)

$$\eta(w) = P_{\theta_{TRUE}}(C = 1 | W = w)$$

Bayes optimal classifier (with reject option):

$$y_{\theta_{TRUE}}^{*,d}(w) = \begin{cases} 1 & \text{if } \eta(w) > 1 - d \\ 0 & \text{if } \eta(w) < d \\ abstain & \text{otherwise, i.e., } d \le \min\{\eta(w), 1 - \eta(w)\} \end{cases}$$

where  $d \in [0, 1/2]$  is the reject cost.

• If  $y_{\theta_{TRUE}}^{*,d}(w) \neq abstain$  [d upper bound on misclassification error]

 $d > \min \{\eta(w), 1 - \eta(w)\} = P_{\theta_{TRUE}}(y^*_{\theta}(w) \neq C) \qquad [error of Bayes optimal]$ Theorem (Chow 1970).

$$\arg\min_{y_{\theta}^{+}} E_{(W,C) \sim f_{\theta_{TRUE}}}[d\mathbb{1}_{y_{\theta}^{+}(W)=abstain} + \mathbb{1}_{y_{\theta}^{+}(W) \neq C, y_{\theta}^{+}(W) \neq abstain}] = y_{\theta_{TRUE}}^{*,d}$$

# Selective binary classification

A selective binary classifier (score) is a pair  $(s_{\theta}, g_{\theta})$ , where  $s_{\theta}()$  is a classifier (score) and  $g_{\theta} : \mathbb{R}^{|W|} \to \{0, 1\}$  is a selection function, which determines when to accept/abstain from using  $s_{\theta}$ :

$$(s_{ heta},g_{ heta})(w) = egin{cases} s_{ heta}(w) & ext{if } g_{ heta}(w) = 1 \ abstain & ext{otherwise} \end{cases}$$

### Support and Risk

The coverage of a selective classifier is  $\phi(g_{\theta}) = E_{(W,C)\sim f_{\theta_{TRUE}}}[g_{\theta}(W)]$ , i.e., the expected probability of the accepted region. The risk w.r.t. a loss function  $\ell_{\theta}$  is  $R(s_{\theta}, g_{\theta}) = E_{(W,C)\sim f_{\theta_{TRUE}}}[\ell_{\theta}(C, W)g_{\theta}(W)]/\phi(g_{\theta})$ .

• Empirical coverage and empirical selective risk:

$$\hat{\phi}(g_{ heta}) = rac{\sum_{i=1}^{n} g_{ heta}(w_i)}{n}$$
  $\hat{r}(s_{ heta}, g_{ heta}) = rac{rac{1}{n} \sum_{i=1}^{n} \ell_{ heta}(c_i, w_i) g_{ heta}(w_i)}{\hat{\phi}(g_{ heta})}$ 

• Selective classification problem: minimize risk while guaranteeing a minimum support c

$$\mathop{arg~\min}\limits_{ heta} R(s_{ heta},g_{ heta}) \hspace{0.1in} ext{s.t.} \hspace{0.1in} \phi(g_{ heta}) \geq c$$

# Soft selective binary classification

A soft selective binary classifier:

$$(s_ heta,g_ heta)(w) = egin{cases} s_ heta(w) & ext{if } k_ heta(w) \geq \pi \ abstain & ext{otherwise} \end{cases}$$

- $k_{\theta}(w)$  is called the *confidence function* 
  - A good confidence function should rank instances based on descending loss, i.e., if k(w) ≤ k(w') then E[ℓ<sub>θ</sub>(C, w)] ≥ E[ℓ<sub>θ</sub>(C, w')].
  - E.g., confidence of the classifier:  $k_{\theta}(w) = \min\{s_{\theta}(w), 1 s_{\theta}(w)\}$
- The inherent trade-off between risk and coverage is summarized by the risk-coverage curve
